

Lumina Desk

DEMO SCRIPT

Two halves. First what a customer sees at the table, then what the restaurant sees behind it. Shoot them in that order — the second only makes sense once the first has landed.

Before you roll. Run `./venv/bin/python tools_doctor.py` — everything should say ok. Open `http://techiesms.local:8000` and log in now, so no PIN screen appears on camera. Leave 20–30 seconds between takes; the free API tier slows down under rapid retries.

Part 1 • The customer

Sitting down

Shot: over your shoulder — table, panel, nothing else

The screen is already showing the restaurant name and three things you could say. No app, no QR code, no menu card.

Ordering

You: *Hey Lumina, one large Margherita and two cold coffees.*

It answers out loud, and the panel redraws with both items, the prices, what they contain, and the running total.

The screen takes about 20 seconds to redraw. That's ePaper, not a bug. Say the number out loud once and the audience accepts it for the rest of the video. Then cut away or speed it up in the edit — never film the wait.

Asking about the food

You: *What's in the cheese stuffed garlic bread?*

It reads the ingredients. Worth saying on camera: this comes out of the menu database, not the model's memory. It isn't allowed to make it up.

You: *Add two of those.*

"Those" works — it knows what you were just talking about.

Changing your mind

You: *Actually, remove one.*

You: *What's my bill?*

The total is computed in Python from the menu. The model never touches a number — that's the line worth repeating.

Paying

You: *I want to pay.*

Shot: the panel with the UPI QR, then your own phone scanning it

The amount is already filled in. One UPI ID, a different amount every bill, no payment gateway. Pay it for real if you can — a live payment landing is worth more than any explanation.

Then the thank-you screen, with a feedback QR that already knows which table you were sitting at.

One more thing worth showing

Action: pull the internet out, on camera

You: *Hey Lumina, one Margherita.*

It still works. Wake word, speech recognition, understanding, the voice and the screen all run on the Pi. Be straight that offline recognition is less accurate — admitting it costs nothing and makes the rest believable.

Part 2 · The kitchen and the back office

Screen recording from here, not a camera pointed at a monitor. Everything lives at one address on the restaurant's WiFi.

The kitchen board

Tickets appear as they're spoken. Wait timers turn amber then red. Allergens are flagged in red on every line. One tap moves a dish New → Preparing → Ready → Served, and the table's own screen updates with it.

Shot: order something at the table, then cut to the ticket appearing

Guest requests get their own banner — "Table 07 needs 2× water" — and stay up until someone marks them delivered.

Changing the menu, live

This is the best single demo in the whole back office. Do it in one shot, no cut:

1. Change a dish's price on the Menu page
2. Immediately ask Lumina what that dish costs
3. The new price comes back

Same for marking something sold out — it stops being orderable straight away. No restart, no redeploy.

Analytics

Revenue today, average ticket, how long an order takes from spoken to served, peak hour, busiest tables, and what people actually order.

Payments

Every bill and how it settled. Payments confirm themselves by reading the merchant's payment emails; there's a webhook for a real gateway and a Mark paid button for when neither applies.

Terminal

Live logs from every service, in the browser. Show yourself debugging a table from a phone while standing in the shop — that's the point of it.

Settings

Assistant on, muted or off. Cloud or fully offline. Tax, UPI ID, the voice and how fast it speaks, wake-word sensitivity, staff PIN. Everything applies within a second.

Worth demonstrating **Muted** specifically: the microphone is genuinely released — the mic ring goes dark — and the table's screen says so instead of inviting someone to talk to something that isn't listening.

What to say, and what not to

SAY	WHY IT LANDS
The model never decides a price.	It's the whole design in six words.
Pull the internet out and it keeps taking orders.	Nobody expects this.
The screen uses no power to hold that bill.	The moment people rewind.
It's running at a real pizza place, with their real menu.	Turns a demo into a product.

Don't say it's perfect. It mishears a dish name sometimes, like every voice system. If that happens mid-take, correct it out loud and keep rolling — that take is better than a clean one, because every voice demo online is suspiciously flawless and everyone knows it.

Rough edges to plan around

THING	WHAT TO DO
ePaper takes ~20 s to redraw	Cut away or speed-ramp. Mention the number once.
The very first word of a reply can clip	Don't subtitle a greeting or make it a hero moment. Every line is written so losing the first word doesn't lose the meaning.
Free API tier rate-limits	20–30 s between takes.
Panel is on USB	The WiFi firmware works, but this router has client isolation on. Don't claim battery on camera unless you've shot it.
Offline is slower	Say so. That it works at all is the feature.

If you want one clip for social

Sit down. Say the order. Cut to the panel showing the bill. No narration, vertical, fifteen seconds. The idea reads without a word of explanation, which is the only thing that travels.
